

<i>Definition</i>	<i>Practices around developing IaC</i>	<i>Build, tests, publish IaC build artifacts</i>	<i>Using IaC to provision infrastructure</i>	<i>Managing running infrastructure</i>	<i>Monitor and measure infrastructure</i>
Area of Practice	Development	Continuous Integration	Provisioning	Management	Observability
Level 3 - Optimizing Focus on process improvement	<ul style="list-style-type: none"> Continual improvement and optimization of IaC based on evolving industry standards 	<ul style="list-style-type: none"> Continuous improvement of tests at various levels 	<ul style="list-style-type: none"> Zero-downtime provisioning of infra Ability to automatically roll back changes Self-service provisioning 	<ul style="list-style-type: none"> Infrastructure is self-healing, self-configurable, and self-optimizing 	<ul style="list-style-type: none"> Metrics are regularly reviewed Metrics are available in real-time Production incidents related to infrastructure are rare and always reviewed
Level 2 - Managed Processes measured and controlled	<ul style="list-style-type: none"> All changes are tracked in an Application Lifecycle Management tool All defects and bugs are tracked in the ALM Code is declarative 	<ul style="list-style-type: none"> Builds are not left broken Changes are always promoted through a consistent path to production 	<ul style="list-style-type: none"> Ability to manually roll back changes quickly and safely 	<ul style="list-style-type: none"> Infrastructure is highly available and fault tolerant Configuration drift is impossible 	<ul style="list-style-type: none"> Automated alerting based on active monitoring IaC processes and practices are documented and available
Level 1 - Consistent Processes characterized and proactive	<ul style="list-style-type: none"> All infrastructure is defined as code All IaC under version control Industry-standard tooling is used to write code 	<ul style="list-style-type: none"> CI Server to pull, build, test, and publish IaC artifacts Automated tests are run for every check-in Test are run in a 'prod-like' environment 	<ul style="list-style-type: none"> Result of an automated delivery pipeline Provisioning is idempotent 	<ul style="list-style-type: none"> Immutable infrastructure (no SSHing into boxes) Infrastructure is reliable and performs predictably 	<ul style="list-style-type: none"> Metrics are calculated automatically but not regularly reviewed Centralized infrastructure monitoring and logging
Level 0 - Repeatable Processes characterized but often reactive	<ul style="list-style-type: none"> Infrastructure partially automated using scripts Not all is checked into VCS Automation doesn't rely on industry-standard tooling 	<ul style="list-style-type: none"> IaC tests are only run locally 	<ul style="list-style-type: none"> Provisioning is scripted but executed ad-hoc 	<ul style="list-style-type: none"> Patching and upgrades are done through provisioning processes 	<ul style="list-style-type: none"> Metrics are defined, but no way to collect or consistently measure
Level -1 - Regressive Processes unrepeatable, poorly controlled, and reactive	<ul style="list-style-type: none"> Nothing is stored in VCS Scripts are stored on infra, local workstations, or as notes 	<ul style="list-style-type: none"> No Continuous Integration Server No written IaC tests No way to test infrastructure before provisioning 	<ul style="list-style-type: none"> Infrastructure is built manually from command line or from a UI Existing infrastructure cannot be easily rebuilt Provisioning new infrastructure is painful and inconsistent 	<ul style="list-style-type: none"> Existing infrastructure is brittle and unreliable Patching and upgrades are done directly on running infra Troubleshooting is done directly on running infrastructure 	<ul style="list-style-type: none"> No defined infrastructure metrics: SLAs, KPIs, CSFs Monitoring and logging done directly on running infra No automated alerting

* Assumes all practices follow security requirements and best practices
